Hypertension Associated with Coarctation (COA) of the Aorta. Case Report from Clinical Experience in Paediatric

Eilaf Mohamednour, and Kirsten Wolffsohn

ABSTRACT

Coarctation of the aorta is a birth defect, in which the aorta becomes narrower than usual and this narrowness differs in the amount from one case to another. Occurring more frequently in boys than girls and the risk increases with family history having bicuspid aortic valve and in Turner syndrome.

It can present with different clinical presentations depending on the severity of the narrowness; weak or no pulse in the feet and blood pressure in the arm much higher than in the legs. The aim of this case report is to emphasize special attention to coarctation of the aorta as a cause of systemic hypertension, delineate the difference diagnostic approach for systemic hypertension in children and adults and stress the importance of doing proper clinical examination of cardiovascular examination and checking the blood pressure even in young children. Such case will help us pay attention to the possibility of COA in children with hypertension.

Keywords: Coarctation, HTN, Secondary HTN, Aorta.

I. CASE REPORT

A lovely 8-year-old girl with no background of medical condition. Referred by her GP due to; left ankle swelling and inability to weight-bearing over it associated with blanching skin rash which later developed into petechial and purpuric rash. Her mother observed that she had becoming more lethargic, and easy getting fatigued coupled with exercise intolerance in the last few months. In addition to experiencing central constant chest pain with no clear obvious cause which took few minutes and settled without medication. Initial differential diagnosis is HSP, then after spiking high-grade fever with increased inflammatory marker sepsis was thought and started on antibiotic. On evaluation she noted to have persistent high blood pressure with sinus tachycardia since admission. After proper physical examination: there is active pericardium with continuous harsh systolic murmur loudest on the back over interscapular space with equal pulse in the upper limbs and absent bilateral femoral pulses. Musculoskeletal system showed; swelling and tenderness around the left leg, left foot and calf muscles with discouloration. Pale, pink mottled with decreased range of movement of left ankle.

Cholesterol Xray and ECG were unremarkable. Chemistry, renal, liver and aldosterone level were all within normal range FBC (16000) CRP (73) coagulation is normal, fibrinogen slightly elevated; urine protein creatinine ratio is 48(high), no protein or blood in the urine. Echo showed; subclavian coarctation of the aorta. Doppler u/s reveals normal flow, MRI ankle, showed infective tenosynovitis with no evidence of arthritis or osteomyelitis.

II. CONCLUSION

Occult aortic coarctation should be suspected in hypertensive young patient. Blood measurement must be part of routine physical examination in children 3 years and older and thoroughly physical examination should be carried out for etiology of secondary hypertension.
